CNS Injury (i.e. Triad) – Suspected NAI
Imaging cannot distinguish nonaccidental injury from accidental injury, or from predisposing or complicating medical conditions.

Skeletal Injury – Suspected NAI
Imaging cannot distinguish nonaccidental injury from accidental injury, or from predisposing or complicating medical conditions, including the Bone Fragility Disorders.

Shaken Baby Syndrome
The Triad

“Shaken Baby Syndrome (SBS) is a form of physical non-accidental injury (NAI) to infants, characterized by acute encephalopathy with subdural and retinal hemorrhages (i.e. the Triad), occurring in the context of inappropriate or inconsistent history and commonly accompanied by other apparently inflicted injuries (e.g. fractures).”

Shaken Baby Syndrome (SBS)

Battered Child Syndrome / Shaken Baby Syndrome
The “Traditional” Literature

- **Caffey J.** Multiple fractures in the long bones of infants suffering from chronic subdural hematoma. Am J Roentgenol 1946; 56: 163-173.

Child Abuse – NAI
“Traditional” Medical Diagnosis

- Injury out of proportion to history (unwitnessed)
- Tearing or shearing of brain, blood vessels, bone.
- Injuries of varying ages
- RH+ SDH + Encephalopathy (the Triad)
- +/- Skeletal Lesions (the Tetrad)

Evidence-Based Medicine
Quality of Evidence (QOE)
Diagnosis or Prognosis

Evidence-Based Medicine
Quality of Evidence (QOE)
Recommendations
Evidence-Based Medicine
Shaken Baby Syndrome
Quality of Evidence (QOE)

• Few published reports merit a rating above class IV.

• Class IV: test not applied in blinded fashion; expert opinion alone; descriptive case series without controls.

• Not basis for standards or guidelines.

• Inconsistent Diagnostic Criteria; Faulty Inclusion Criteria; Circular Logic; Conviction and Confession based.

Rules of Evidence – Standards for Admissibility of Expert Testimony

• Frye Standard - testimony generally accepted in the relevant scientific community.

• Daubert Standard (Kumho) - assessment of scientific reliability of testimony.

• Civil Action - money at risk; “preponderance of evidence”.

• Criminal Action - life or liberty; due process; innocent until proven guilty “beyond a reasonable doubt” vs. “clear and convincing evidence”; constitutional right to confront accusers; “burden of proof” on the prosecution.

• SBS cases – Expert defines SBS / NAI as presence of injury (e.g. the Triad) without sufficient historical explanation; unconstitutionally shifts burden to defendant to prove the expert theory wrong.

Texas v. Hurtado (Daubert), Udashen, Sperling 2006.
Lyons. SBS. Utah Law Rev 2003;1109.

Head Injury in NAI Prosecution

• SDH + RH + Encephalopathy = SBS / NAI [the “Triad”]

• Shaking alone in otherwise healthy child can cause SDH leading to death.

• Never due to short fall.

• Immediately symptomatic, i.e. “no lucid interval.”

• Symptoms in child with prior head injury = newly afflicted injury and not spontaneous rebleed (e.g. benign extracerebral collections).

• Last caretaker always guilty (“Unwitnessed”).

Tearing of Brain & Veins

Head Injury in NAI
Prosecution

• Shaking alone in otherwise healthy child may cause SDH leading to death.
• Otherwise, such injury requires:

  “Force equivalent to motor vehicle accident or a 2-story fall.”

\[
F = MA
\]

Force = Mass \times Acceleration

Evidence Base
Shaken Baby Syndrome
Biomechanics - The Brain

• Caffey J. Multiple fractures in the long bones of infants suffering from chronic subdural hematoma. Am J Roentgenol 1946; 56: 163-173.
• Caffey J. The whiplash shaken infant syndrome: manual shaking by the extremities with whiplash-induced intracranial and intraocular bleedings, linked with residual permanent brain damage and mental retardation. Pediatrics 1974;54, 1.
Caffey 1972 Whiplash Shaking

“Our evidence, both direct and circumstantial, indicates that manual whiplash shaking of infants is a common primary type of trauma in the so called Battered Infant Syndrome”.

“Current evidence, though manifestly incomplete and largely circumstantial, warrants a nationwide educational campaign on . . . the potential pathogenicity of habitual . . . shaking of infants . . .”

[Caffey cites Guthkelch]

Child Abuse Centers Established (e.g. Kempe, Chadwick)

Caffey. The whiplash shaken infant syndrome: manual shaking by the extremities with whiplash-induced intracranial and intraventricular bleedings, linked with residual permanent brain damage and mental retardation. Pediatrics 1974;54; 1.

Guthkelch 1971 Infant SDH

Whiplash Injury

“This suggests that in some cases repeated acceleration-deceleration rather than direct violence is the cause of the haemorrhage, the infant having been shaken rather than struck by his parents”.

[Guthkelch cites Ommaya]

Ommaya 1968 Whiplash Injury

Rear-end auto collision simulation.

Adult rhesus monkeys on a sled.

Measure angular accelerations head on neck, without head impact.

Results: Brain injury -19; Neck injury-11.

40g Threshold for intracranial injury (concussion, subdural hemorrhage, shear injury). Caffey & Guthkelch not realize such injury thresholds may not be attained in SBS.

Duhaime et al 1987 SBS

1 month old infant ATD model subjected to adult shakes and impacts.

“All shakes (11g) fell below injury thresholds . . ., while impacts (52g) spanned concussion, subdural hematoma, and diffuse axonal injury ranges.”
“Severe head injuries commonly diagnosed as shaking injuries require impact to occur and that shaking alone in an otherwise normal baby is unlikely to cause the shaken baby syndrome.”

Autopsy series: all fatal cases (13) had signs of blunt head impact (more than half noted only at autopsy); all with uncontrollable increased intracranial pressure.

“Shaken-Impact Syndrome”

Prange 2003 Falls, Shakes, Impacts

1.5 month old infant model subjected to minor falls, shakes, inflicted impacts.

“In general, peak angular acceleration and maximum change in angular velocity increased with increasing fall height and surface hardness”.

“These findings suggest that inflicted impacts against hard surfaces may be more frequently associated with clinically significant inertial brain injuries than vigorous shaking or falls from less than 1.5-m”.

“In addition, there are no data showing that the peak angular acceleration and maximum change in angular velocity of the head experienced during shaking and inflicted impact against unencased foam is sufficient to cause SDHs or TAI in an infant”.

Chris Van Ee Ph.D. Design Research Engineering (www.dreng.com);

Evidence Base

Shaken Baby Syndrome

Biomechanics - The Neck

“Thus, while it is possible to produce trauma in an infant by shaking, e.g. SDH, particularly when shaking is prolonged and repeated at intervals, the injuries would include the cervical cord and spine, but not the brain case, nor contusions in the cerebrum or cerebellum if no impact was also imposed.”

“Head acceleration and velocity levels commonly reported for SBS generate forces that are far too great for the infant neck to withstand
without injury . . and can potentially cause severe, if not lethal, spinal cord or brain stem injury . . at levels well below those reported for the SBS.”

Biomechanical Evidence Base
Conclusions & Recommendations

- **Shaking** may theoretically cause brain injury if associated with cervical spinal cord injury.
- **Short-distance falls** (or any impact, accidental or NAI) can produce brain injury.
- In addition to fall height, impact surface and type of landing are important factors.
- **Head-first impacts** in young infants are the most dangerous.
- **Should always do both** Brain and Cervical Spine CT, as well as MRI (STIR).
- Imaging may not distinguish accidental from nonaccidental injury?

2 yM SCIWORA: Partial High Cervical Cord Transection, SAH, SDH, RH, and Hypoxic-Ischemic Brain Injury (CT, Path, Biomech).

Evidence Base
Head Injury in NAI
Neuropathology

Geddes et al – Neuropathology
of Inflicted Head Injury

“Young Infant”

- 37 / 53: infants < 9 mo. age
- Shaken only 8 (1 admission).
- Apnea, respiratory distress (ALTE)
- **Old injury** (15)
  - Retinal Hem’s, fracture, thin SDH
  - Increased ICP / swelling
- **Hypoxic-ischemic axonal brain injury (no TAI !!)**
- **Traumatic axonal brainstem / cord injury (impact in all)**

Geddes J et al. Dural Haemorrhage (DH) in Non-traumatic Infant Deaths

- Autopsy series
- 50 cases without trauma
- < 5 months of age
- **Infection - 6**
- **Hypoxia-ischemia – 26**
- **Infection + HI – 8**
- **SIDS – 4**
- **C/W SBS – 3**

Geddes et al. Dural Vascular Plexus Haemorrhage (DH) in Non-traumatic Infant Deaths

- **Common Features**: severe hypoxia-ischemia, cerebral venous hypertension, arterial hypertension, brain swelling, venous immaturity / fragility and increased permeability.

- **Result**: intracranial venous dural hemorrhage [+ retinal hemorrhage].

- **Also**: hypoperfusion followed by reperfusion, especially via dural arterial supply with dural hemorrhage (no blood-brain-barrier).

- Coagulopathy.

- “**The Unified Hypothesis**” (i.e. the **Cascade**).

Dural Border Cell Layer/Subdural Compartment & Dural Vascular Plexus

- The **DBC** is approximately 8 microns thick
- The **DBC** is the “**weakest link**” in dural/arachnoid interface due to scarcity of tight junctions and prominent interstitial spaces.

Presumed NAI with Triad

1yM Glutaric Acidopathy

Type 1

Fig.13 12m infant with triad & alleged NAI. Glutaric Acidopathy Type 1. CT (a) & T2 MRI (b) show bilateral SDH of varying age (long arrows), wide sylvian fissures, plus basal ganglia and cerebral white matter abnormalities (short arrows).

Fig. 15 16m with Triad (right RH) and alleged NAI; also, short fall with right scalp impact. CT (a) shows left sylvian arachnoid cyst (c) and right hyperacute SDH (arrows). T2 MRI (b) 2 days later shows acute right SDH (long arrows) and smaller left sylvian arachnoid cyst (c) with subdural hygroma (short arrows).

Neuropathology + Biomechanical Evidence Base

Conclusions

• Shaking may theoretically cause brain injury if associated with cervical spinal cord injury.

• Impact may produce direct or indirect brain injury (accidental or NAI).

• Brain edema with thin SDH (dural vascular plexus origin) may reflect Hypoxia-Ischemia + Cascade (accidental or NAI).

• Brain edema with thin SDH may result from medical causes (e.g. Hypoxia-Ischemia + Cascade) from any cause of ALTE.

• Should always do both Brain and Cervical Spine CT, as well as MRI.

• Imaging may not distinguish accidental from nonaccidental injury, or from predisposing or complicating medical conditions.

Evidence Base for Short Falls & Lucid Intervals - “Sutures!”

Malignant Edema with Fatal Progression

Malignant Edema
Lucid Intervals vs. Fatal Progression
Clinical Series +Neuropathology + Biomechanical Evidence Base
Conclusions

• Significant head injury, including death, may result from low fall levels (or any Impact, accidental or NAI).

• Such injury may be associated with a lucid interval (i.e. caretaker blamed for delay).

• The lucid interval invalidates the premise that the last caretaker is always responsible in alleged NAI.

• In other cases, the injury may result in immediate deterioration with malignant edema & progression to death.

• Predispositions including Genetic?

• Imaging may not distinguish nonaccidental from accidental injury.

Alleged NAI with Triad: 9 w/o Birth Trauma

- Re-hemorrhage may occur in an old SDH without recent trauma and be associated with a lucid interval [Sutures II].

SDH occurs in benign extracerebral collections.
• **Old SDH** may date back to **Birth**.

• **Serial head circumference** measurements, caregiver education, preventive measures, attention to nonspecific symptoms, early imaging “before the crash”.

• **Imaging** may not distinguish nonaccidental injury from accidental injury.

---

**Head Injury in NAI - Prosecution**

**Retinal Hemorrhage (RH) only occurs in SBS / NAI.**

**Evidence-Based Challenges**

---

**Head Injury in NAI - Prosecution**

**Retinal Hemorrhage only occurs in SBS / NAI.**

**Evidence-Based Challenges**

---

**Evidence-Based Challenges to SBS / NAI**

as the only cause for the “Triad”

- **Plunkett 2001.** RHs in 2/3 of the fatal accidental head injuries.
- **Gilles 2003.** RHs reflect increased intracranial pressure after head injury.
- **Lantz 2006.** RH with perimacular folds in a case of crush injury to an infant’s head.
- **Goldsmith 2004.** Extensive RHs; videotaped fatal short.
- **Forbes AAPOS 2007.** RHs in 60% of accidental infant EDH.
- **Obi AAPOS 2007.** RHs, schisis, folds in both AI & NAI.
- **Brown AAPOS 2007.** Dog shaking / killing of 2 kittens, 1 rabbit with no eye findings at autopsy.
- **Binenbaum AAPOS 2007.** No RHs in 3-5 day old piglets subjected to rotational acceleration / deceleration 40x inflicted ‘shaking’ reported by Prange 2003.
- **Emerson. 2007.** Finds no support for the vitreous traction hypothesis for RH.
- **Gilliland MGF 2006.** Use of the triad of scant SDH, brain swelling, and retinal hemorrhages to diagnose non-accidental injury is not scientifically valid. NAME 2006.
Reactions to the Evidence-Based Challenges

- AAO removes SBS Resource Website for revision on RHs June 2007.
- AAP revised position statement on RHs to be released Spring 2009.
- AAP 2001 position paper expires without renewal.
- NAME 2001 position paper expires without renewal.

Evidence Base

Conclusions

- The Triad: RH + SDH + Edema not specific for NAI.
- May occur with accidental trauma.
- May occur with medical conditions.
- Must consider Predisposing Risk Factors.
- Must consider Multifactorial, Synergistic, & Cascade Effects.

Dural +/- Retinal Hemorrhage

Differential Diagnosis

- Trauma (AI vs. NAI)
- Hypoxia-Ischemia / Reperfusion
- Parturitional Injury
- Venous thrombosis
- Apnea / Choking /Respiratory Arrest
- Infection & Post-infectious (e.g. vaccinal)
- Status Epilepticus
- Hematologic (Coagulopathies)
- Vitamin Deficiency (C, D, K).
- Metabolic Disorders (e.g. GA1, Menkes)
- Vascular / Connective Tissue Diseases (e.g. OI).
- ECMO
- Congenital Heart Disease
- Cervical Spinal Cord Injury
- Multifactorial / Synergistic (including CPR)
- No Body Knows

CNS Injury (i.e. Triad) – Suspected NAI

Imaging can not distinguish nonaccidental injury from accidental injury, or from
predisposing or complicating medical conditions.

Mandatory Reporting - Suspected NAI

Recommendations

- Should do Brain and Cervical Spine CT.
- Strongly recommend Brain and Cervical Spine MRI (ASAP).
- Provide detailed description of imaging findings.
- **Differential Diagnosis.**
- May not distinguish fractures from suture variants (3DCT?).
- Caution regarding timing estimates, especially CT.
- Direct reporting to the primary healthcare professional.
- Recommendations for further imaging (e.g. skeletal survey).

- **Impression:** “The imaging findings can not distinguish nonaccidental from accidental injury or from predisposing and complicating medical conditions.”

CT & MRI in Alleged NAI

Limitations

- Barnes P. Imaging of the CNS in Suspected or Alleged NAI. ASPNR Gyrations Newsletter 2007; 2: 5-7 <www.aspnr.org>

**Timing of Hemorrhage (Thrombosis)**

CT Limitations

- High density (i.e. clotted, acute to subacute) 3 hr. to 7-10 days;
- Not differentiate hemorrhage v. thrombosis (e.g. venous)
- Iso-Hypodense (i.e. nonclotted):
  - Hyperacute (<3 hrs.)
  - Chronic (> 7-10 days)
  - BECC or subdural hygroma (acute or chronic)
- Blood levels unusual in acute stage except coagulopathy.
- Not distinguish acute hemorrhage from re-hemorrhage upon BECC or chronic SDH
- Interhemispheric SDH not characteristic for NAI
- Mixed-density SDH may occur in AI.

Hyperacute right SDH vs. chronic SDH with re-hemorrhage?
+/- Unilateral Edema = NAI
(Myth?)

Timing of Hemorrhage (Thrombosis)
MRI Limitations

- **Hyperacute** (< 12 hr.): T1 iso-hypointense, T2 hyperintense;
- **Acute** (1-3 days): T1 iso-hypointense, T2 hypointense;
- **Early Subacute** (3-7 days): T1 hyperintense, T2 hypointense;
- **Late Subacute** (7-14 days): T1 hyperintense, T2 hyperintense;
- **Early Chronic** (> 14 days): T1 hyperintense, T2 hyperintense;
- **Late Chronic** (> 1 – 3 months): T1 isohypointense, T2 hypointense).

Timing of Hemorrhage (Thrombosis)
MRI Limitations

- **Mixed intensity** - problematic regarding timing.
- **Blood Levels** - subacute hemorrhage vs. coagulopathy.
- **Timing guidelines** - sediment not supernatant.
- **CSF Component** - BECC v. acute SDH v. hyperacute SDH v. chronic SDH, SDHG.
- **GRE** - iron-sensitive but not assist with timing unless matched with T1, T2, and CT.
- **GRE / SWI** - sensitive to venous thromboses (e.g. cortical, medullary, subependymal) that may not detected by MRV.
- **FLAIR** - sensitive, but not specific for hemorrhage unless matched with T1, T2, GRE, CT.

**BECC vs. Chronic SDH with Re-hemorrhage vs. Acute Subdural Hygroma + Hematoma**
Child Abuse – Nonaccidental Injury (NAI)
Recommendations
“A Compassionate Approach”

Case # 1

- 19 y/o pair phones 911: 8 m/o boy in resp. distress 3y/o sibling boy also at home.
- Mother and father physicians at work; EMT responds, CPR, intubation unsuccessful.
- ER: Child unresponsive, posturing, bag ventilation. Pupils fixed, dilated. Extensive RH / macular folds. No signs of trauma; No spontan. movements, increased tone.
- IV access, intubation; CBC, clotting studies, blood gases normal; Negative prior medical history; No history of trauma; Child irritable that day; A little “rough” handling by au pair.
- CT: mixed density right convexity and interhemispheric SDH, edema, herniation, right occipital skull fracture, scalp swelling?; No MRI; Skeletal Survey - healing right distal radius fracture 2-4 wks. old.
- Emergency craniotomy for hyperacute SDH; Ventilator dependant infant dies 5 days later; Postmortem confirms fracture, SDH, infarctions.
- Au pair charged with first degree murder, in custody >1 year. Battle of experts at trial - new injury vs. old injury with rebleed (not admissible: child fell out of shopping cart on to head 1 mo. PTA; sibling with # arm fractures in past).
- Au pair convicted of manslaughter, sentenced to time served, and released.

CT: Hyperacute / Acute SDH

Case # 2:

- 41 y/o physician father phones 911 (social worker mother at dentist); 5 m/o girl (29 wk. premi, IVF; DPT-2, Hib-2, 1 wk PTA, fussy); respiratory distress, shaken, CPR, EMT response;
- ER: status Sz, intubated; High WBC, low HCT; abnormal PTT, fibrinogen; Bilateral RH with fibrosis (ROP);
- CT: asymm. cerebral low Ds, loss of GWD, and enhancement; high Ds + enhancement IHF / falx / tent. / DVS; high and low density SA and SD collections;
- CTV: nonopacified segments of SSS, nonopacified adjacent cortical veins (hemorrhages, thromboses, infarctions, subdural collections, communicating hydrocephalus, meningoencephalitis / venous thrombosis); no MRI; skeletal survey negative;
- Brain death at 3 days; death at 3 wk; autopsy: normal neck, cx spine; no skeletal injuries; neuropath – widespread postmortem necrosis & small hemorrhages, perivascular inflammatory cellular infiltration, venous thrombosis, meningeal fibrosis;
- Appeal, conviction, appeal.

Dural Venous Sinus Thrombosis. Hemorrhages / thromboses (a), enhancing cortical infarctions (b), & thrombosis superior sagittal sinus (c, d).
